Environmental Flows emerged to guide ecosystem health

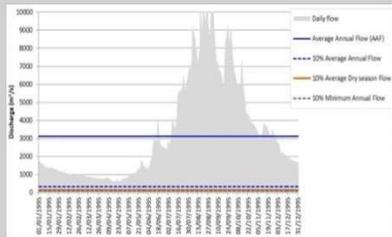

1970

Evolution of EFlows discipline

2020

Hydrological

Q₉₅; 10% AAF

Hydraulic

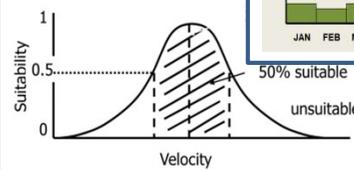

Wetted perimeter

Left bank

Right bank

Habitat

IFIM; PHAB

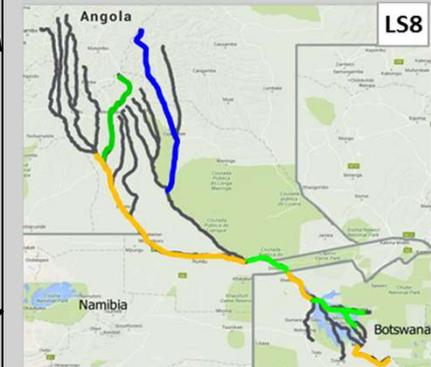

Holistic

BBM; Benchmarking

Ecosystem/social models

DRIFT; RANA-ICE, CaSiMiR

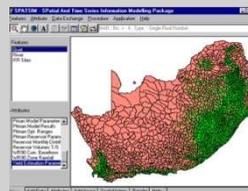

Forces pushing:

- Black box
- Ecosystems
- Social concerns
- Negotiations
- Capacity building
- Monitoring targets

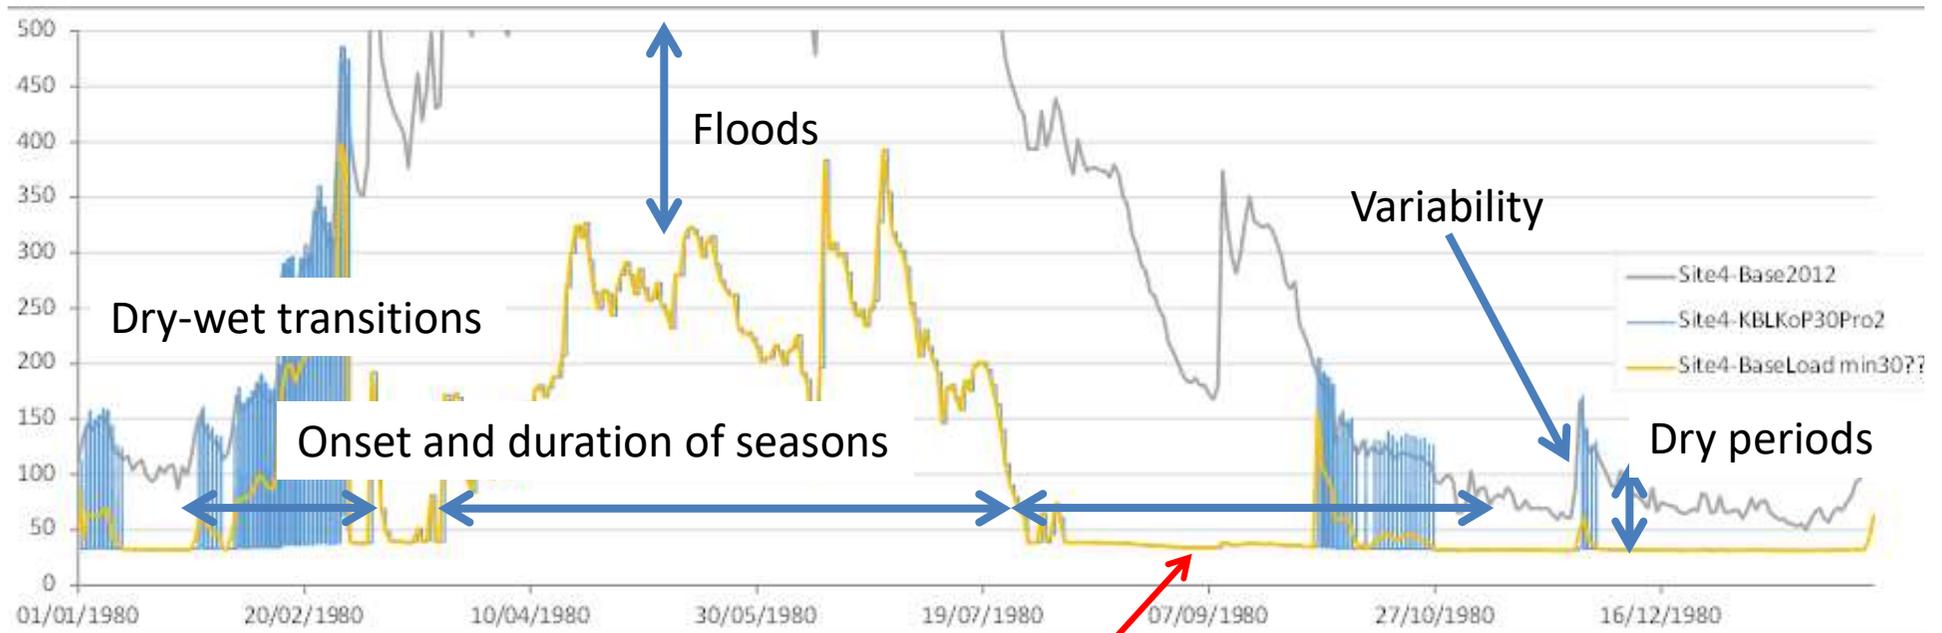

Rapid Frameworks

Desktop; ELOHA

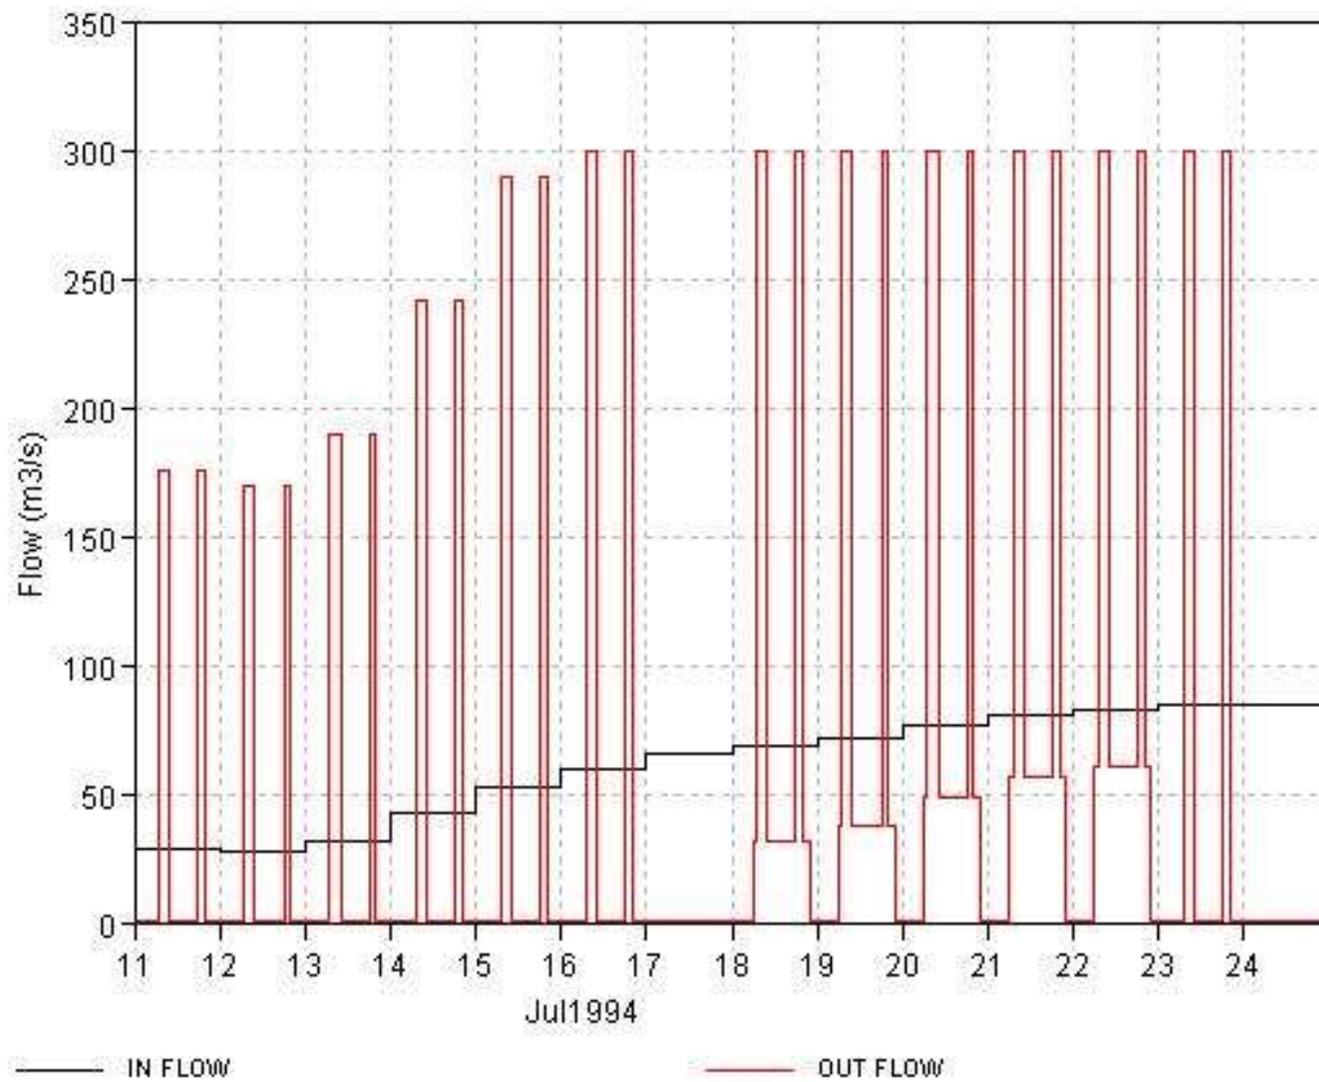

Hydrological methods:

e.g., %AAF rule

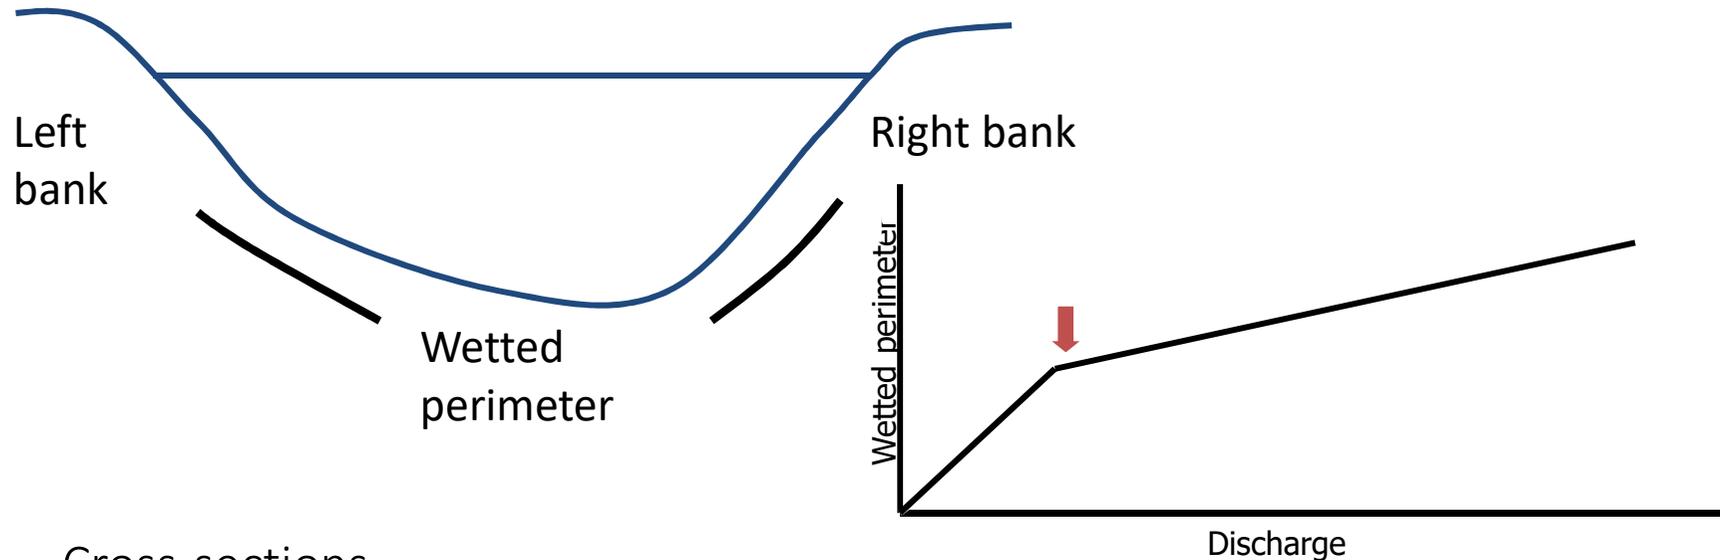

20% AAF

Hydraulic-rating methods:

e.g., Wetted perimeter method

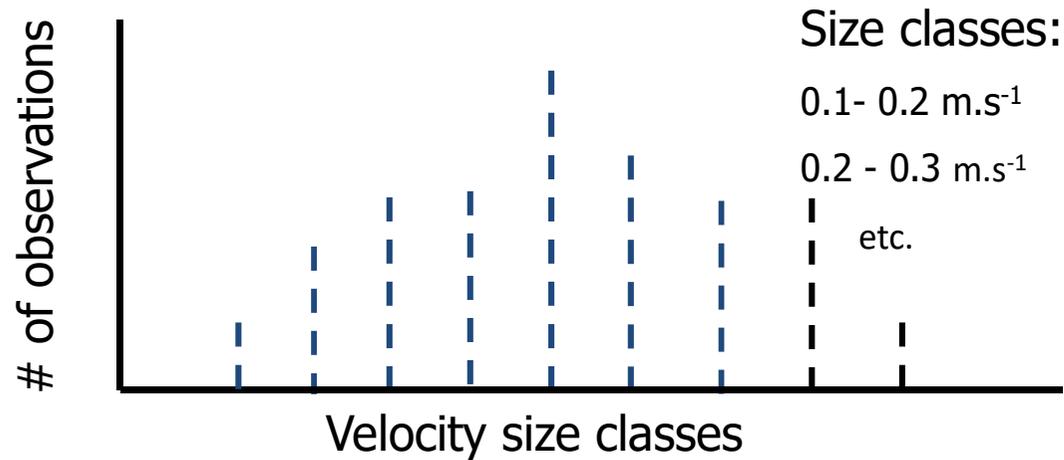

- Cross-sections
- Create wetted perimeter vs discharge plot
- Look for inflection point - assumes this is where area of aquatic habitat starts to decline rapidly
- BUT:
 - there may be more than one inflection point
 - does not reveal details of habitat

Habitat-rating methods

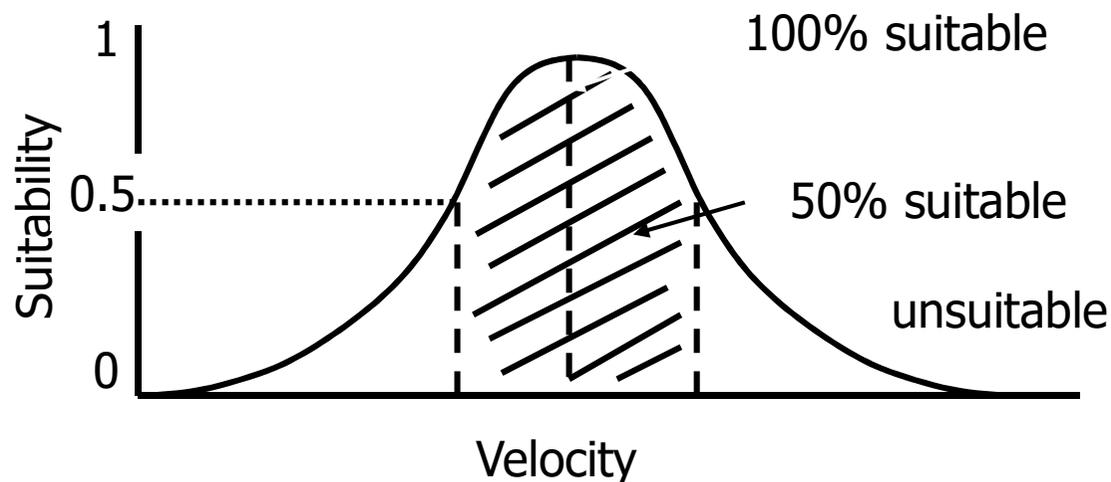

e.g. Instream Flow Incremental Methodology (IFIM)

Allocate values to size classes and create a frequency plot

4. Normalise by allocating value of 1 to the highest frequency class

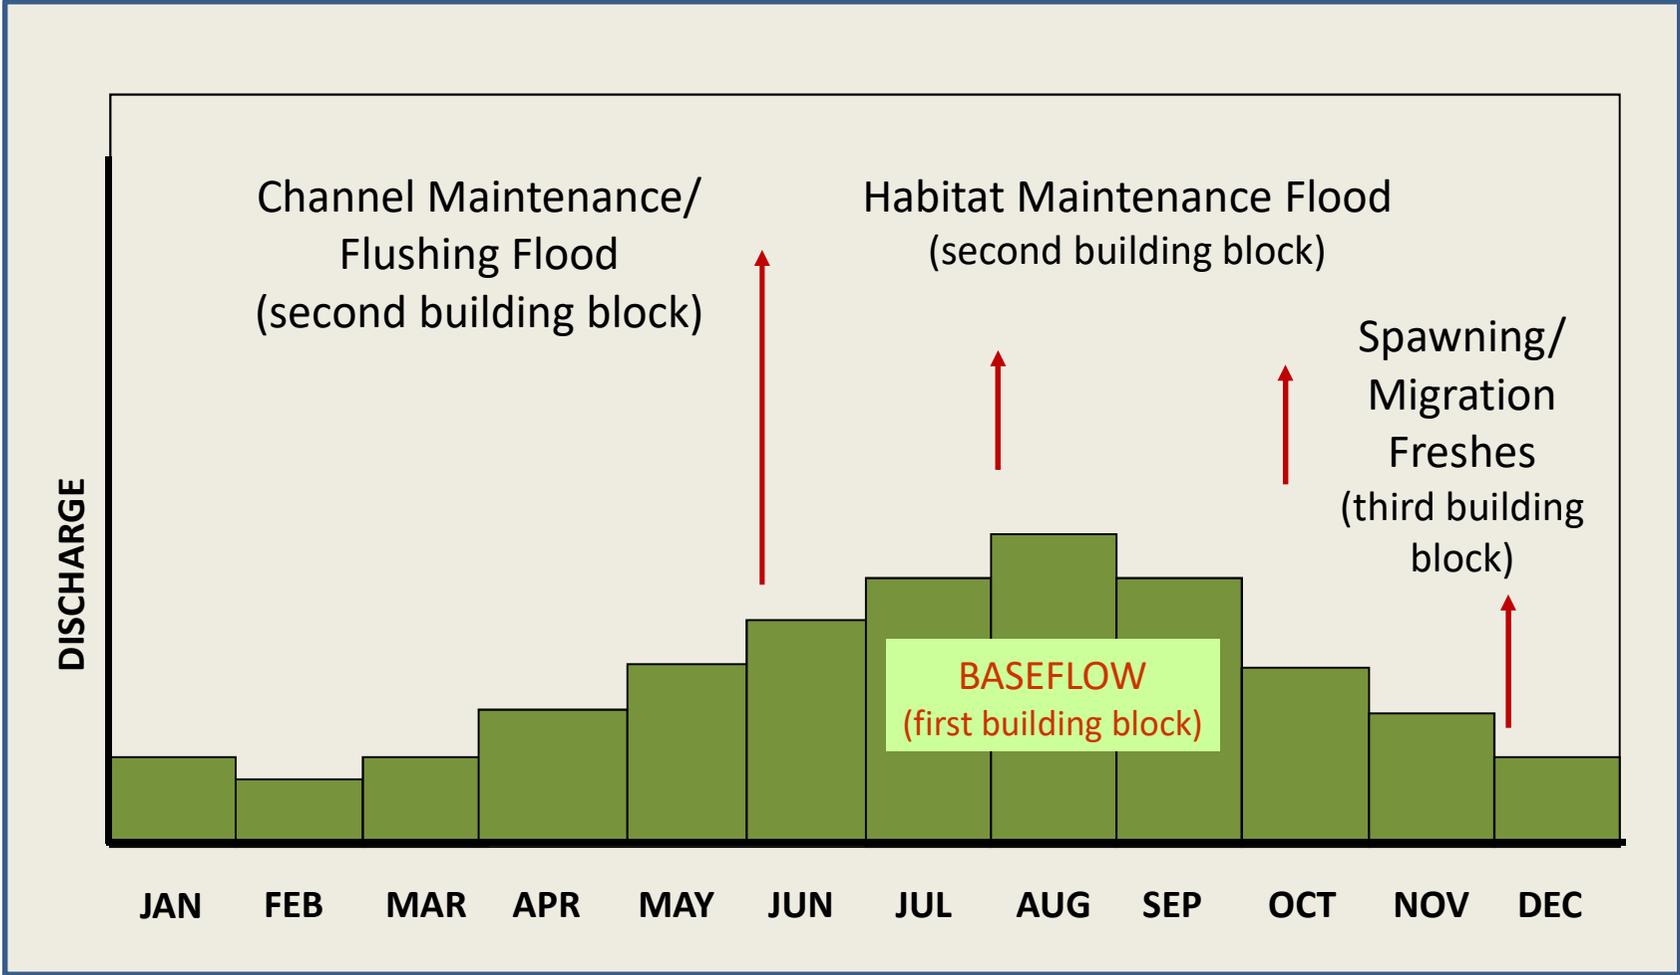

This is an SI (Suitability Index) curve describing the current speed in which a named species was most often found

Holistic Methods:

e.g., Building block methodology

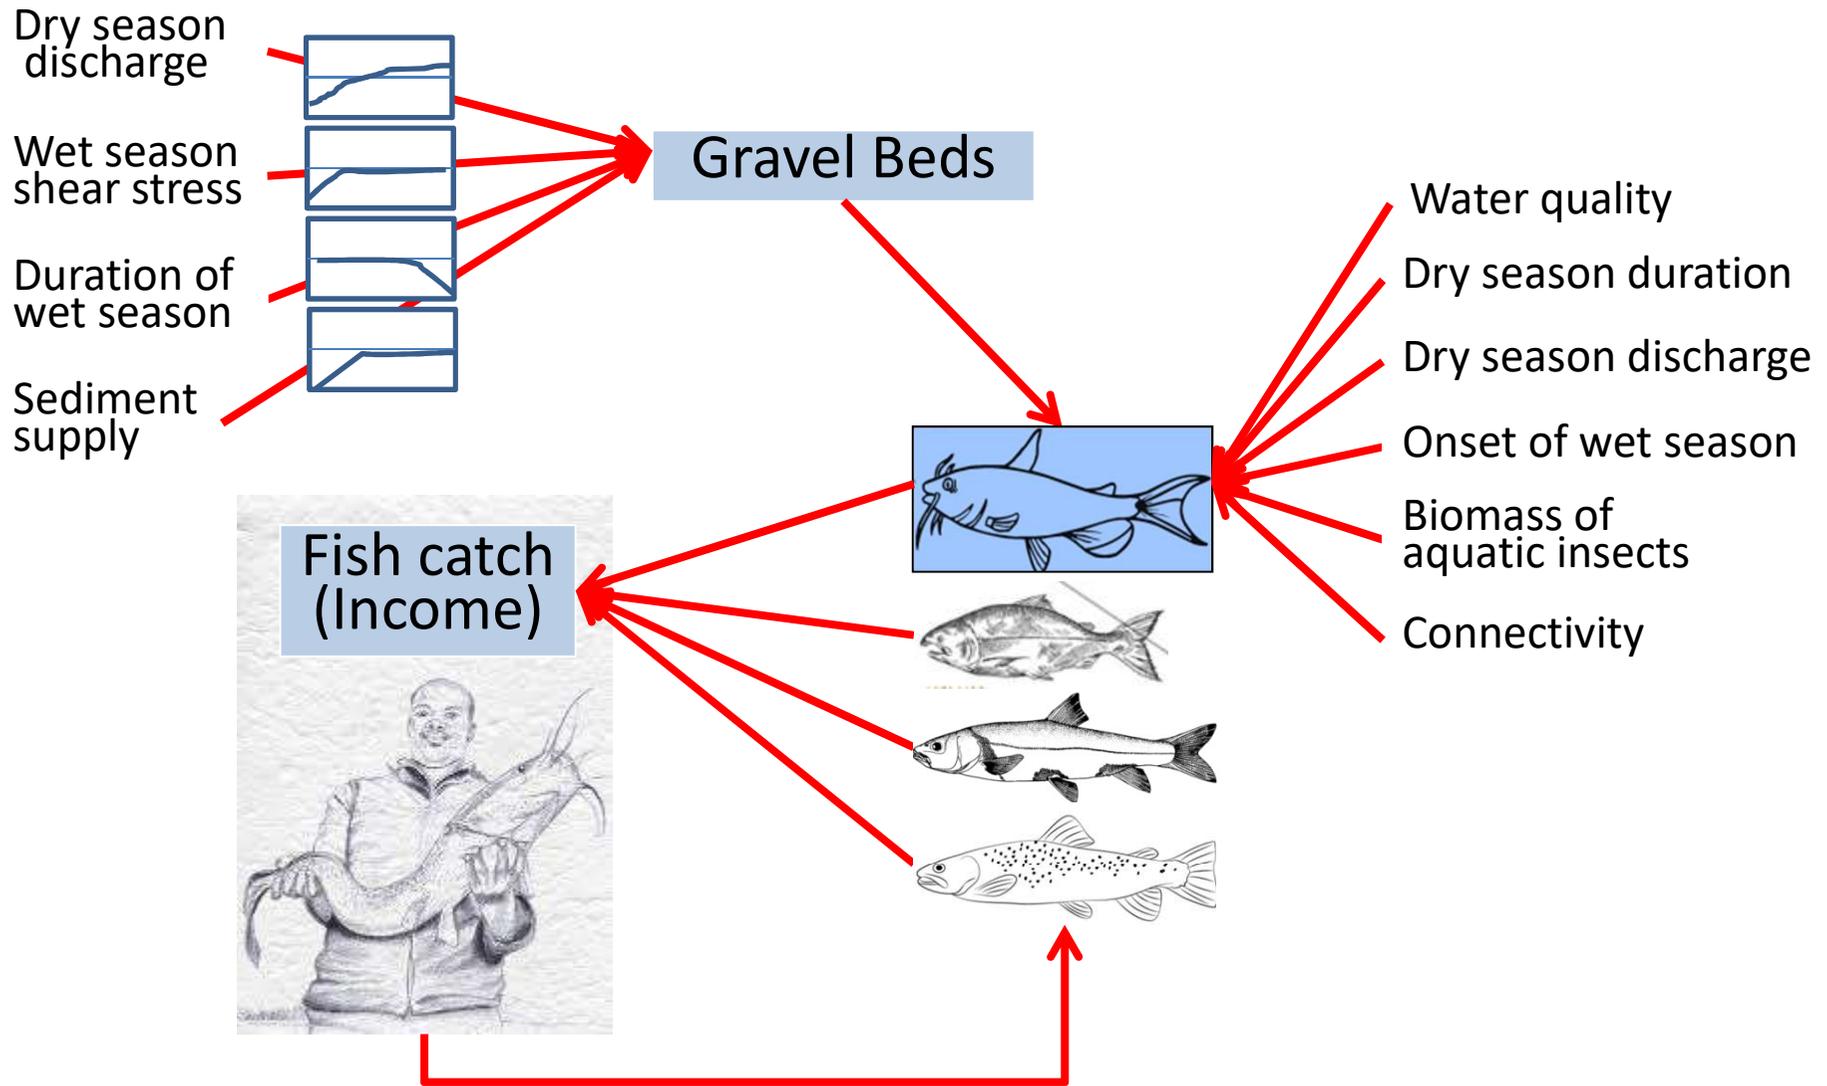

- Based on expert opinion
- Uses a team of biophysical specialists (*hydrology, hydraulics, fluvial geomorphology, water chemistry, vegetation, invertebrates, fish, water birds, social*)
- Focuses on discrete flow events to support habitat and biota in a given condition

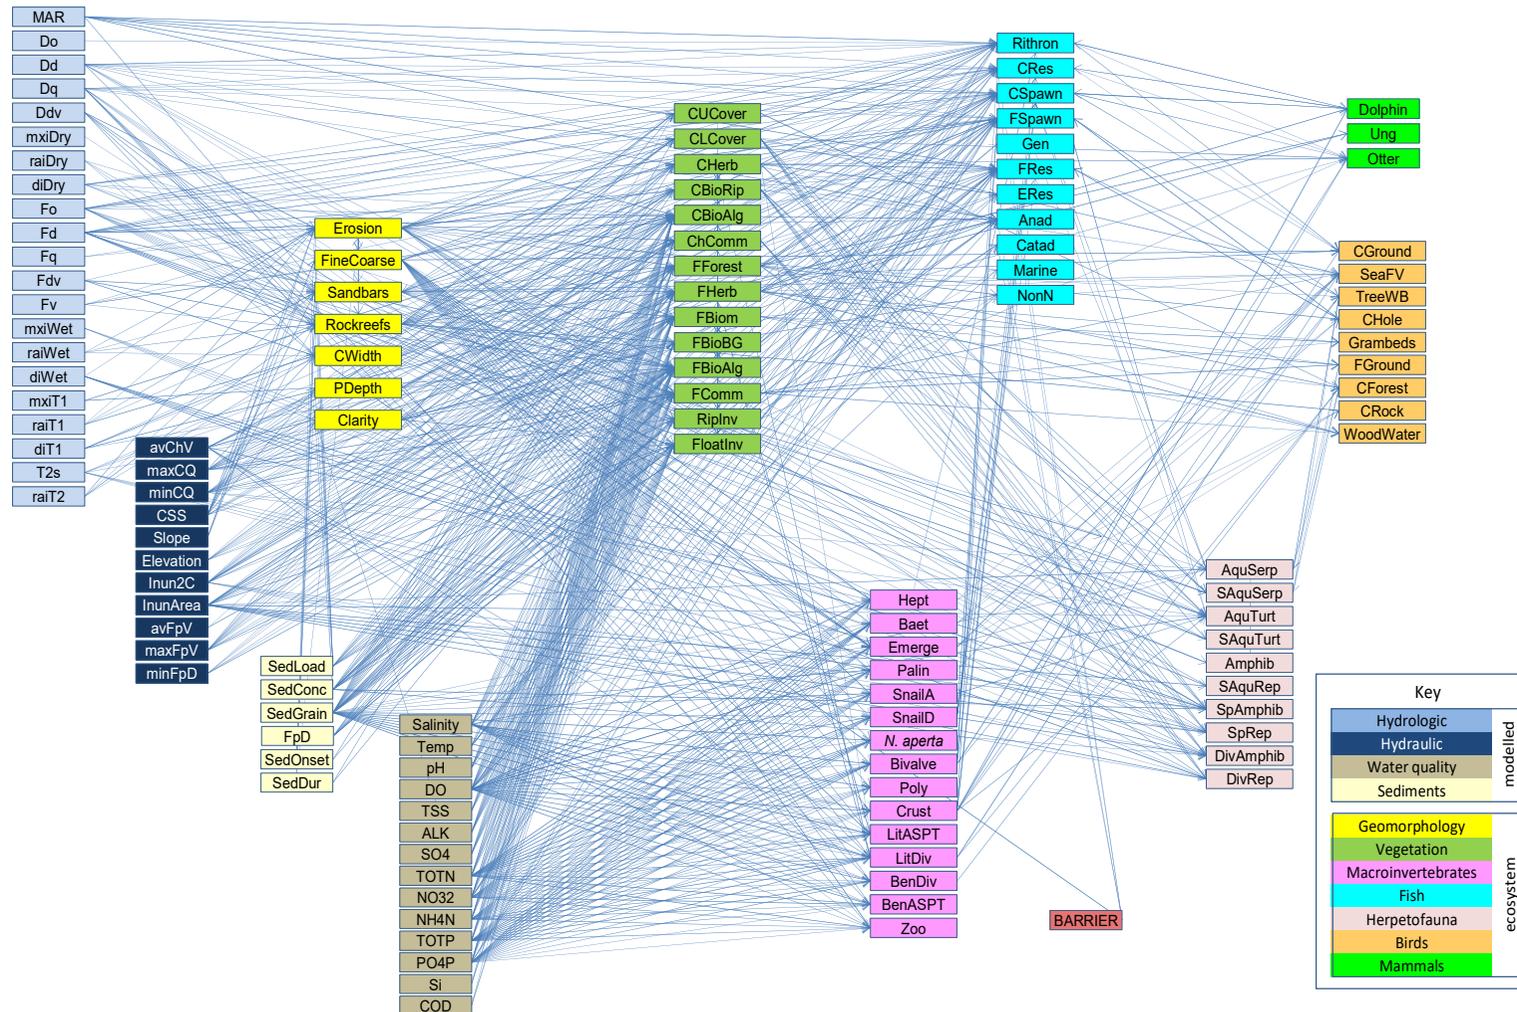

Eco-social Model Methods:

e.g., DRIFT

- Incorporates aspects of Wetted perimeter, IFIM and BBM
- Time-series based – responds to temporal changes
- Does not recommend an EFlows regime
- Aims to answer “What if” questions
- Defines relationships between suite of driving and responding indicators

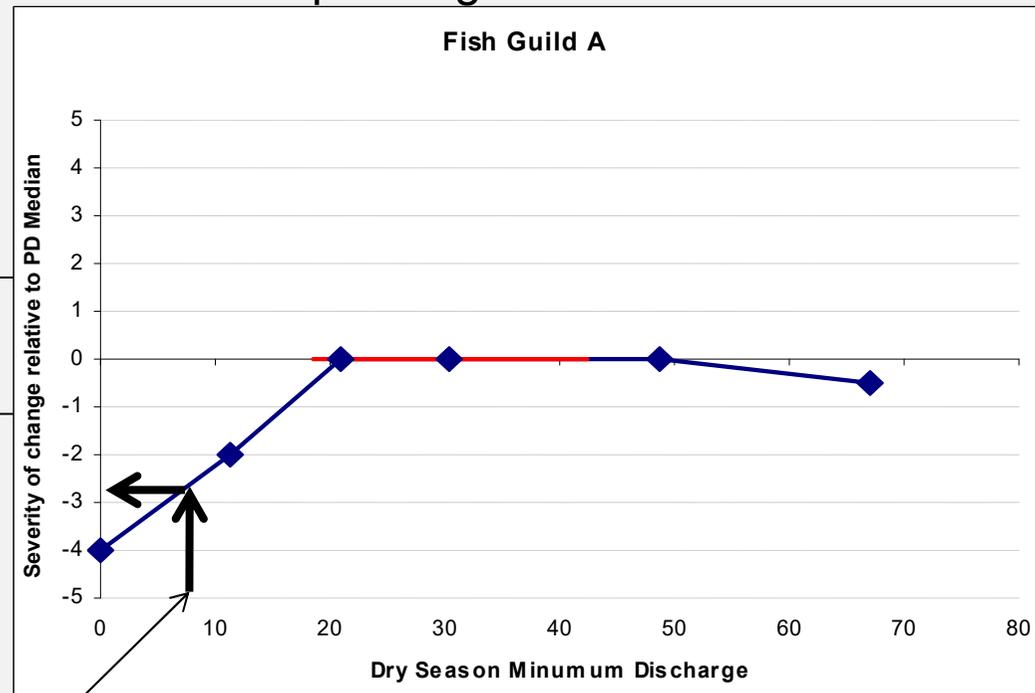

A simplified eco-social model that is true to the complexity of river ecosystems and social uses

External modelled time series

Transformed into time series of driving indicators

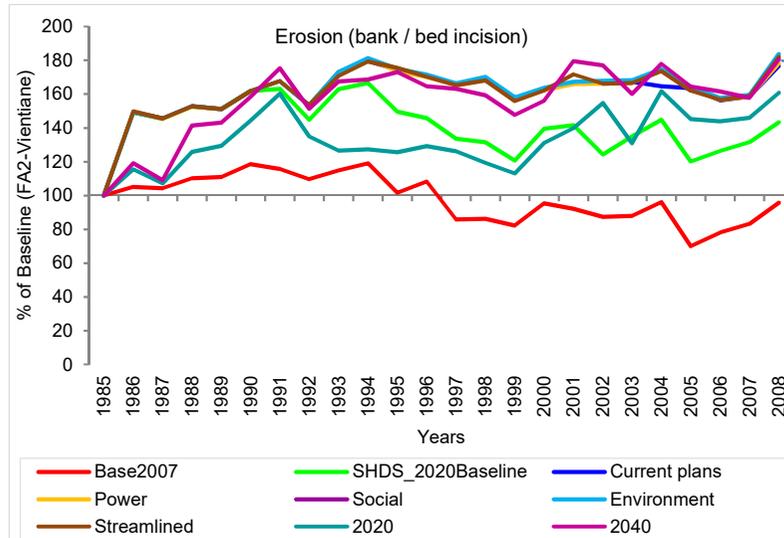

Each responding indicator

Curves combined using multi-criteria decision analysis procedures

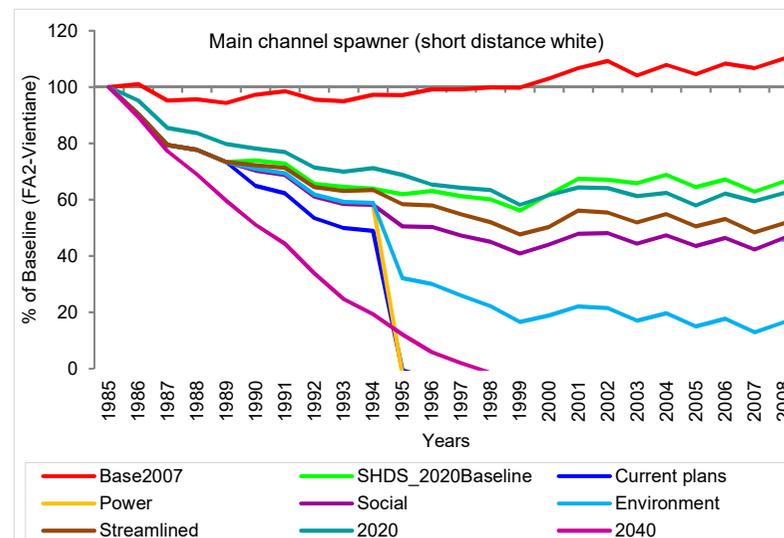

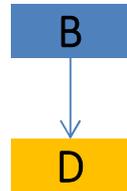

Scenario: Dry season minimum discharge for each year

DRIFT basic output is annual time series of relative change per indicator

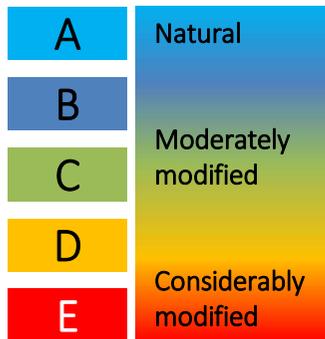

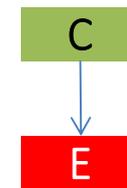

80% increase in erosion

'Health' of overall Habitat

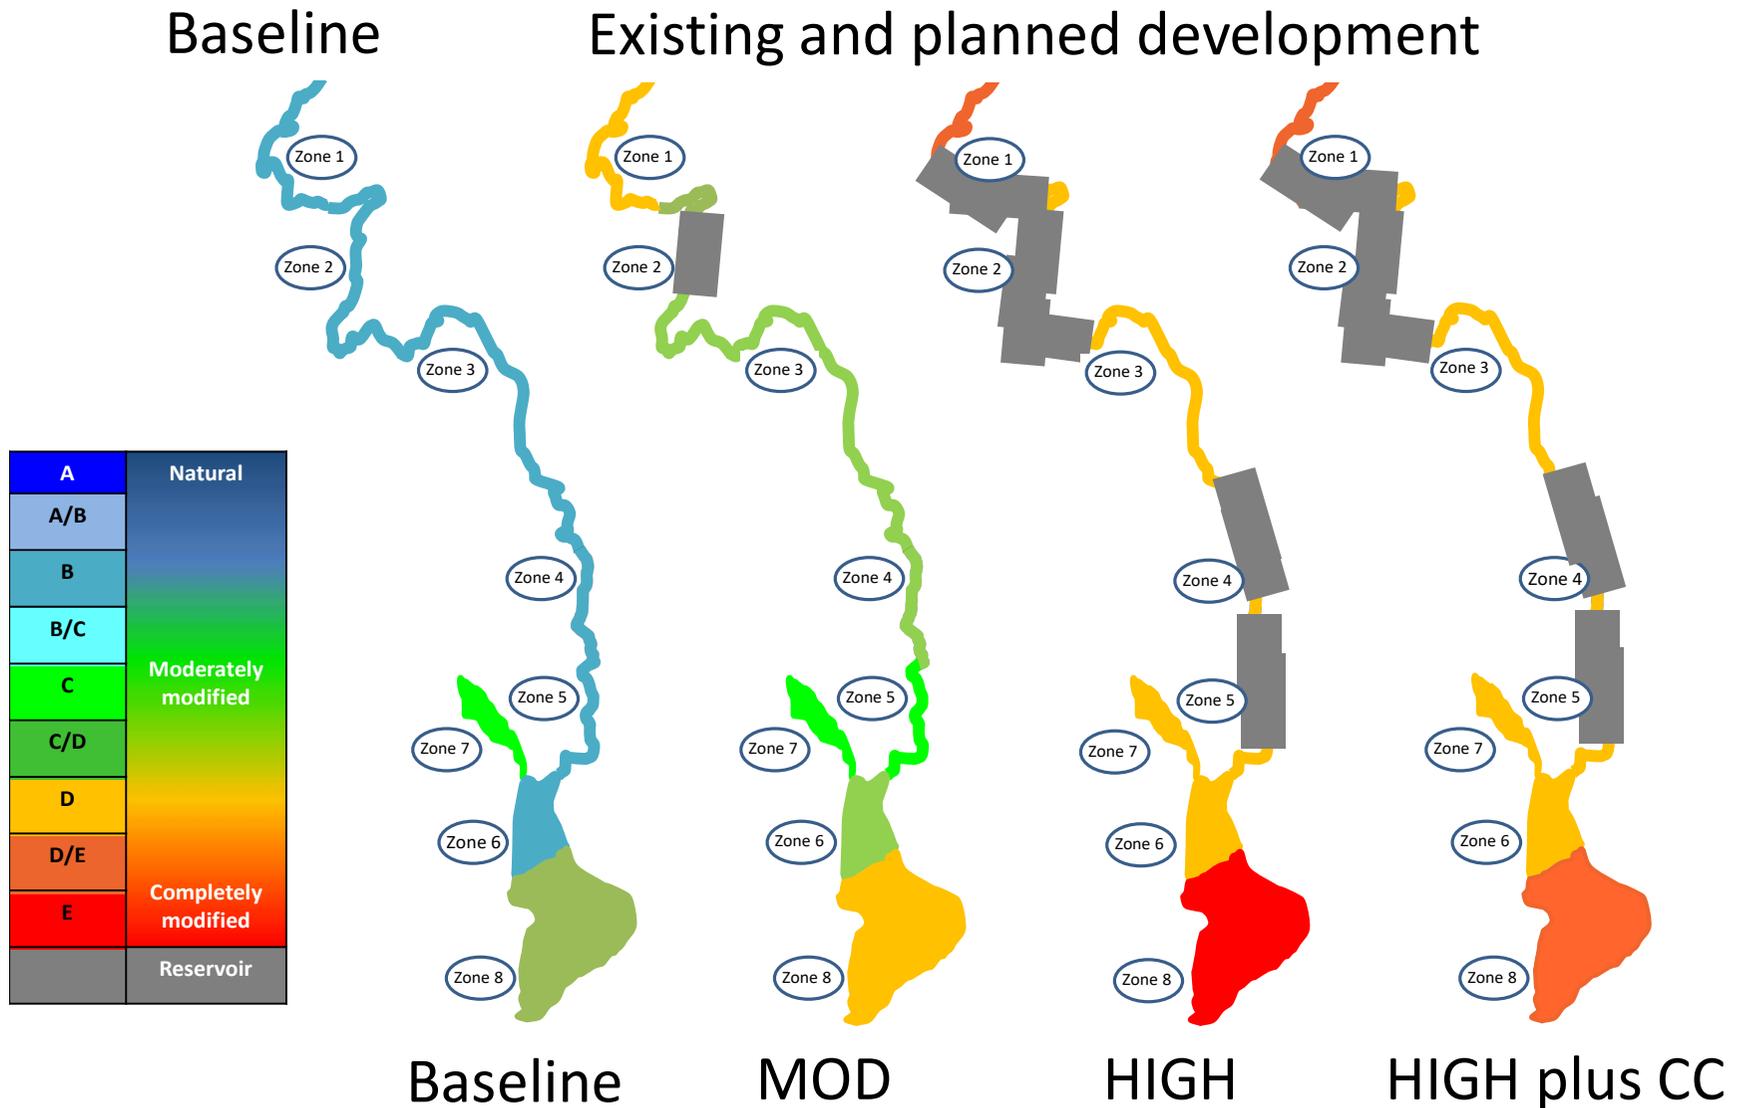

50% reduction in white fish

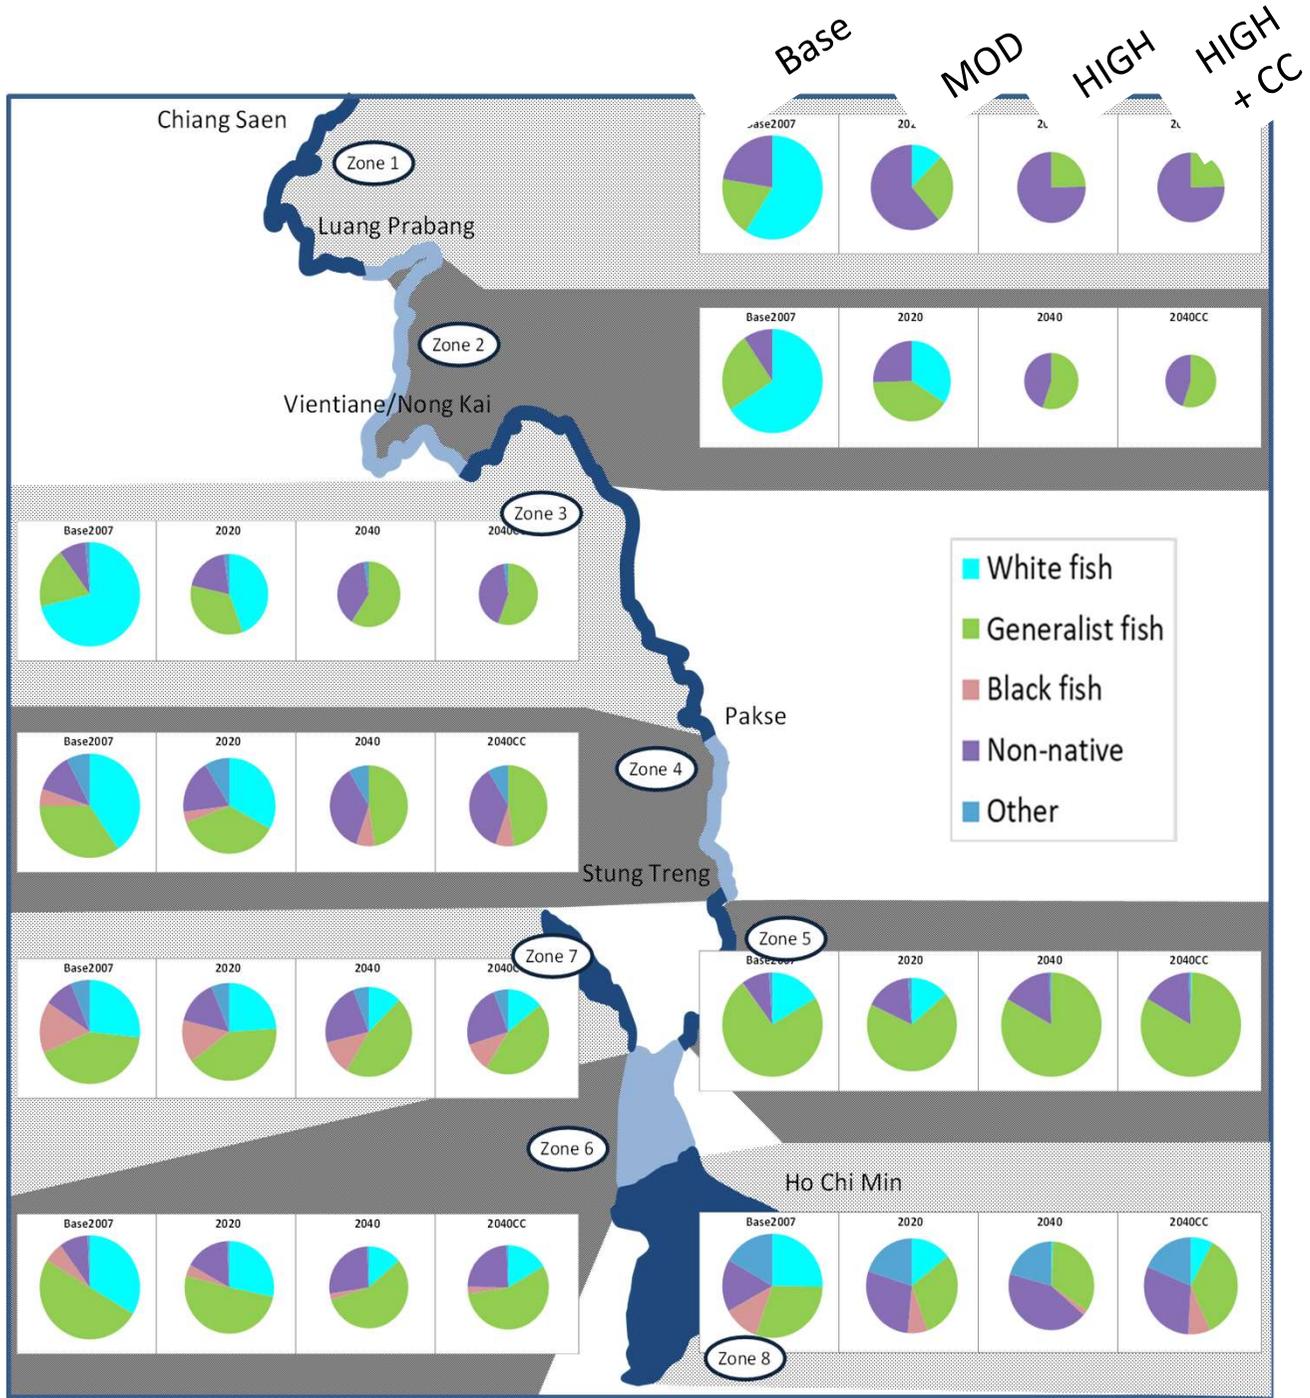

Health of fish community

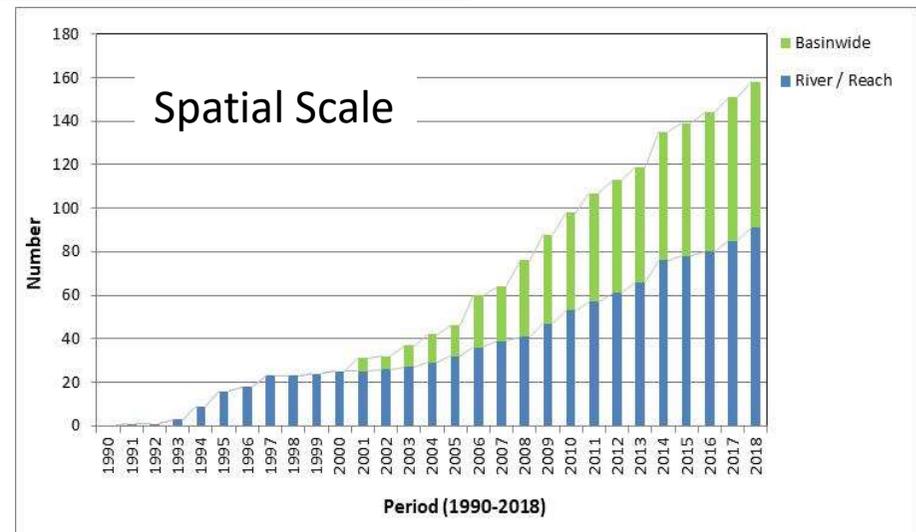

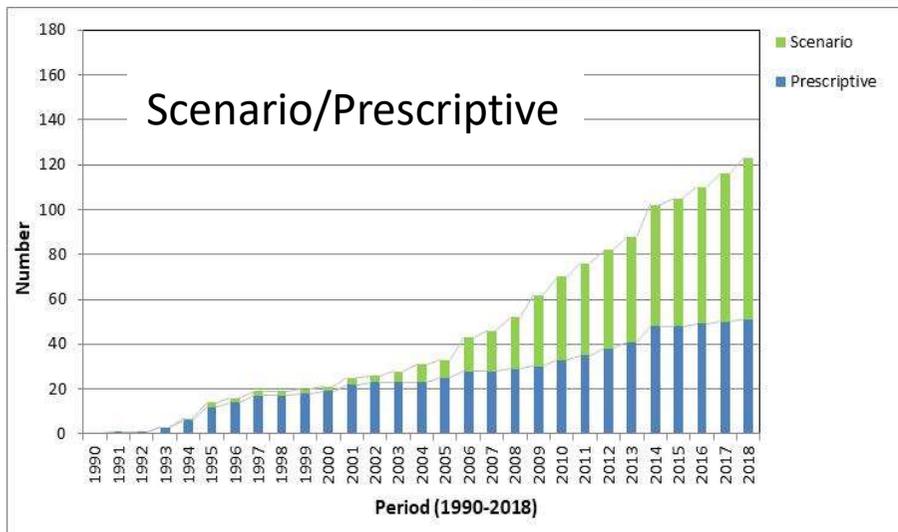

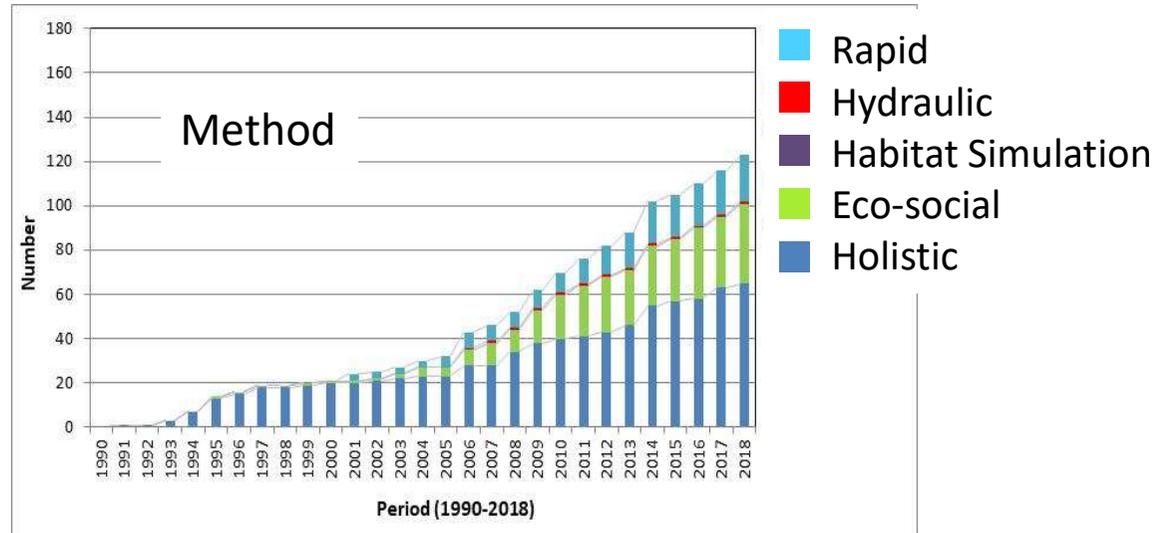

Scenarios: impacts of development (*or restoration*) on whole ecosystem condition

... and on individual resources

Trends in EFlows Assessment in Southern Africa

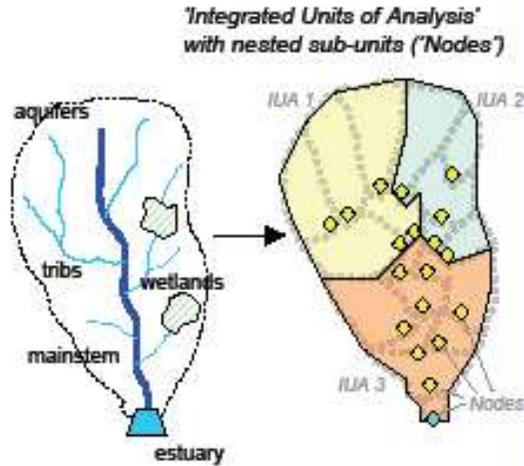

SOUTH AFRICAN WATER RESOURCE CLASSIFICATION SYSTEM (WRCS)

1. Delineate the catchment

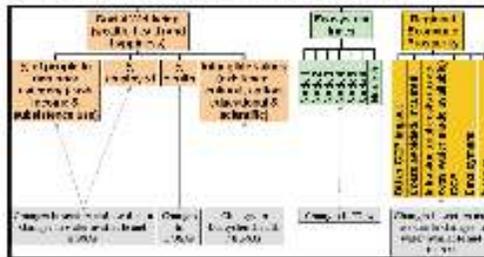

2. Link economic + social value to ecosystem condition and water use

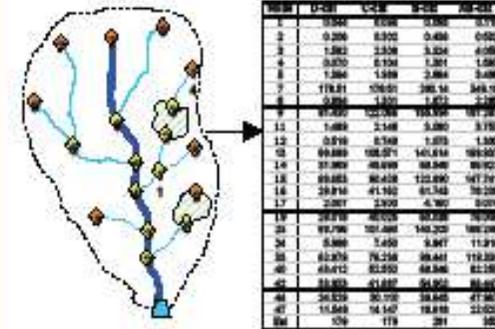

Outcome: a set of quantitative relationships that specify how different levels of

- water use,
- ecological integrity, and
- ecosystem goods and services

affect economic value and social wellbeing.

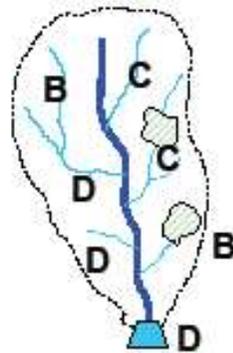

3. Quantify the Ecological Water Requirements at each node

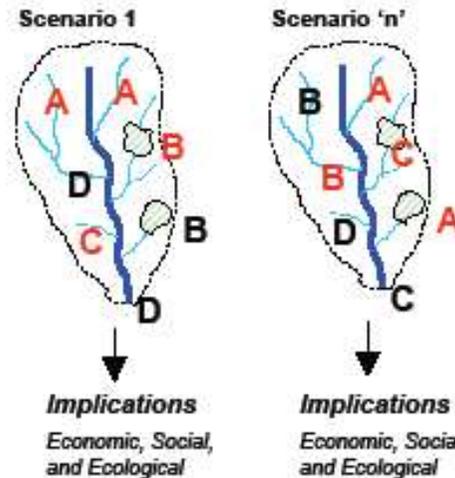

Outcome: Table of EWRs for each node at varying levels of ecological integrity (AB, B, C, D)

4. Set a 'baseline configuration' for ecological sustainability...

...then generate scenarios.

5. Evaluate scenario implications

6. Stakeholder workshops

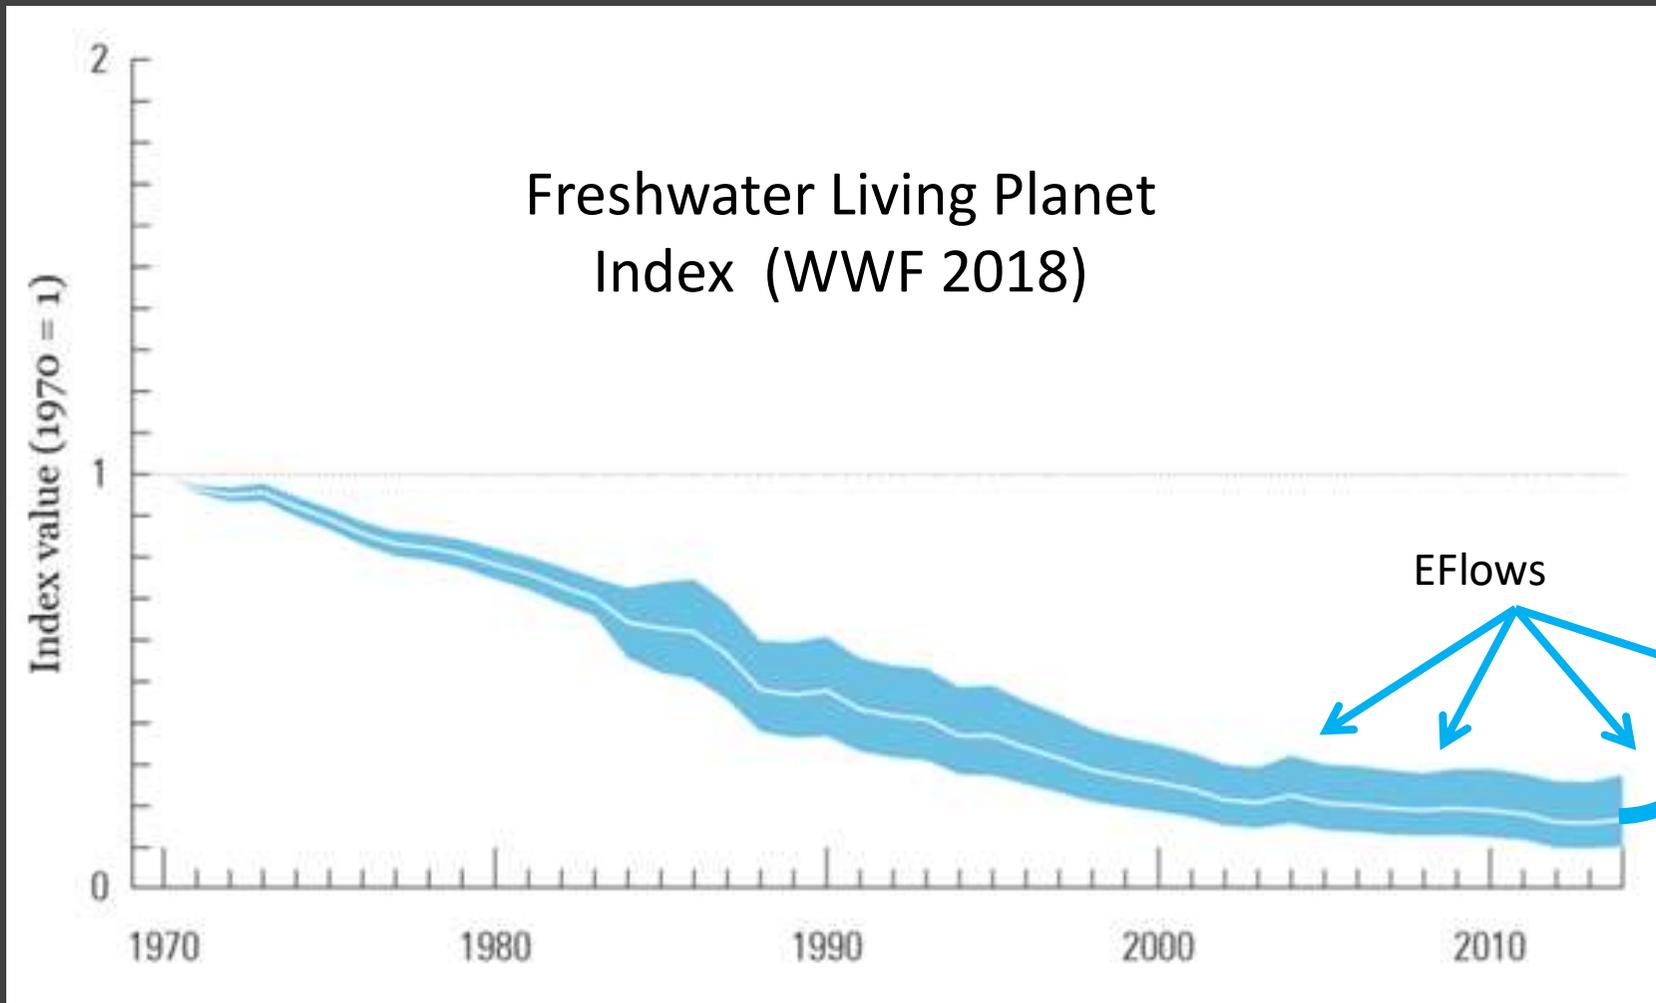

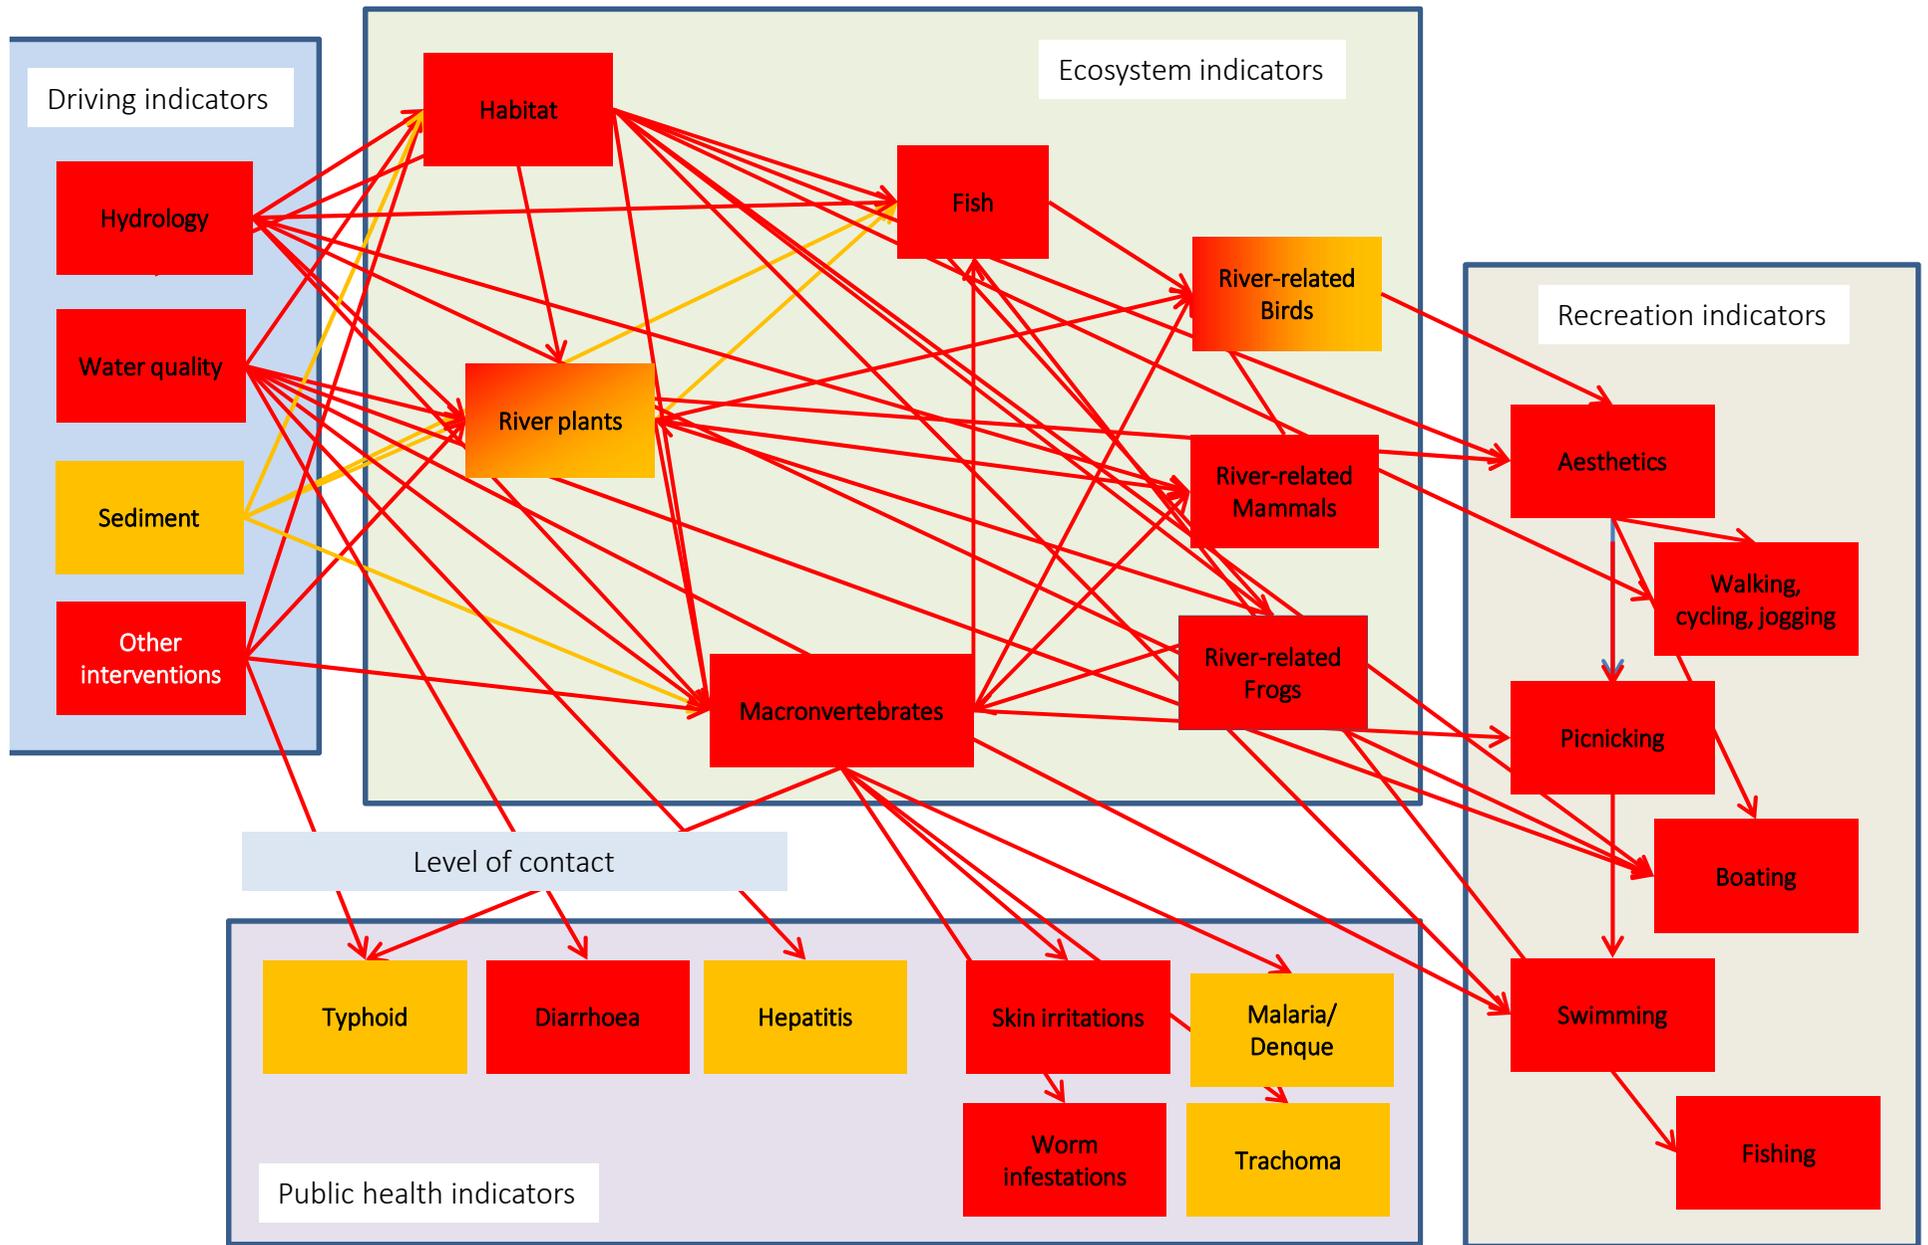

Stakeholders comment on the scenarios and their implications, and may also generate new options for consideration.

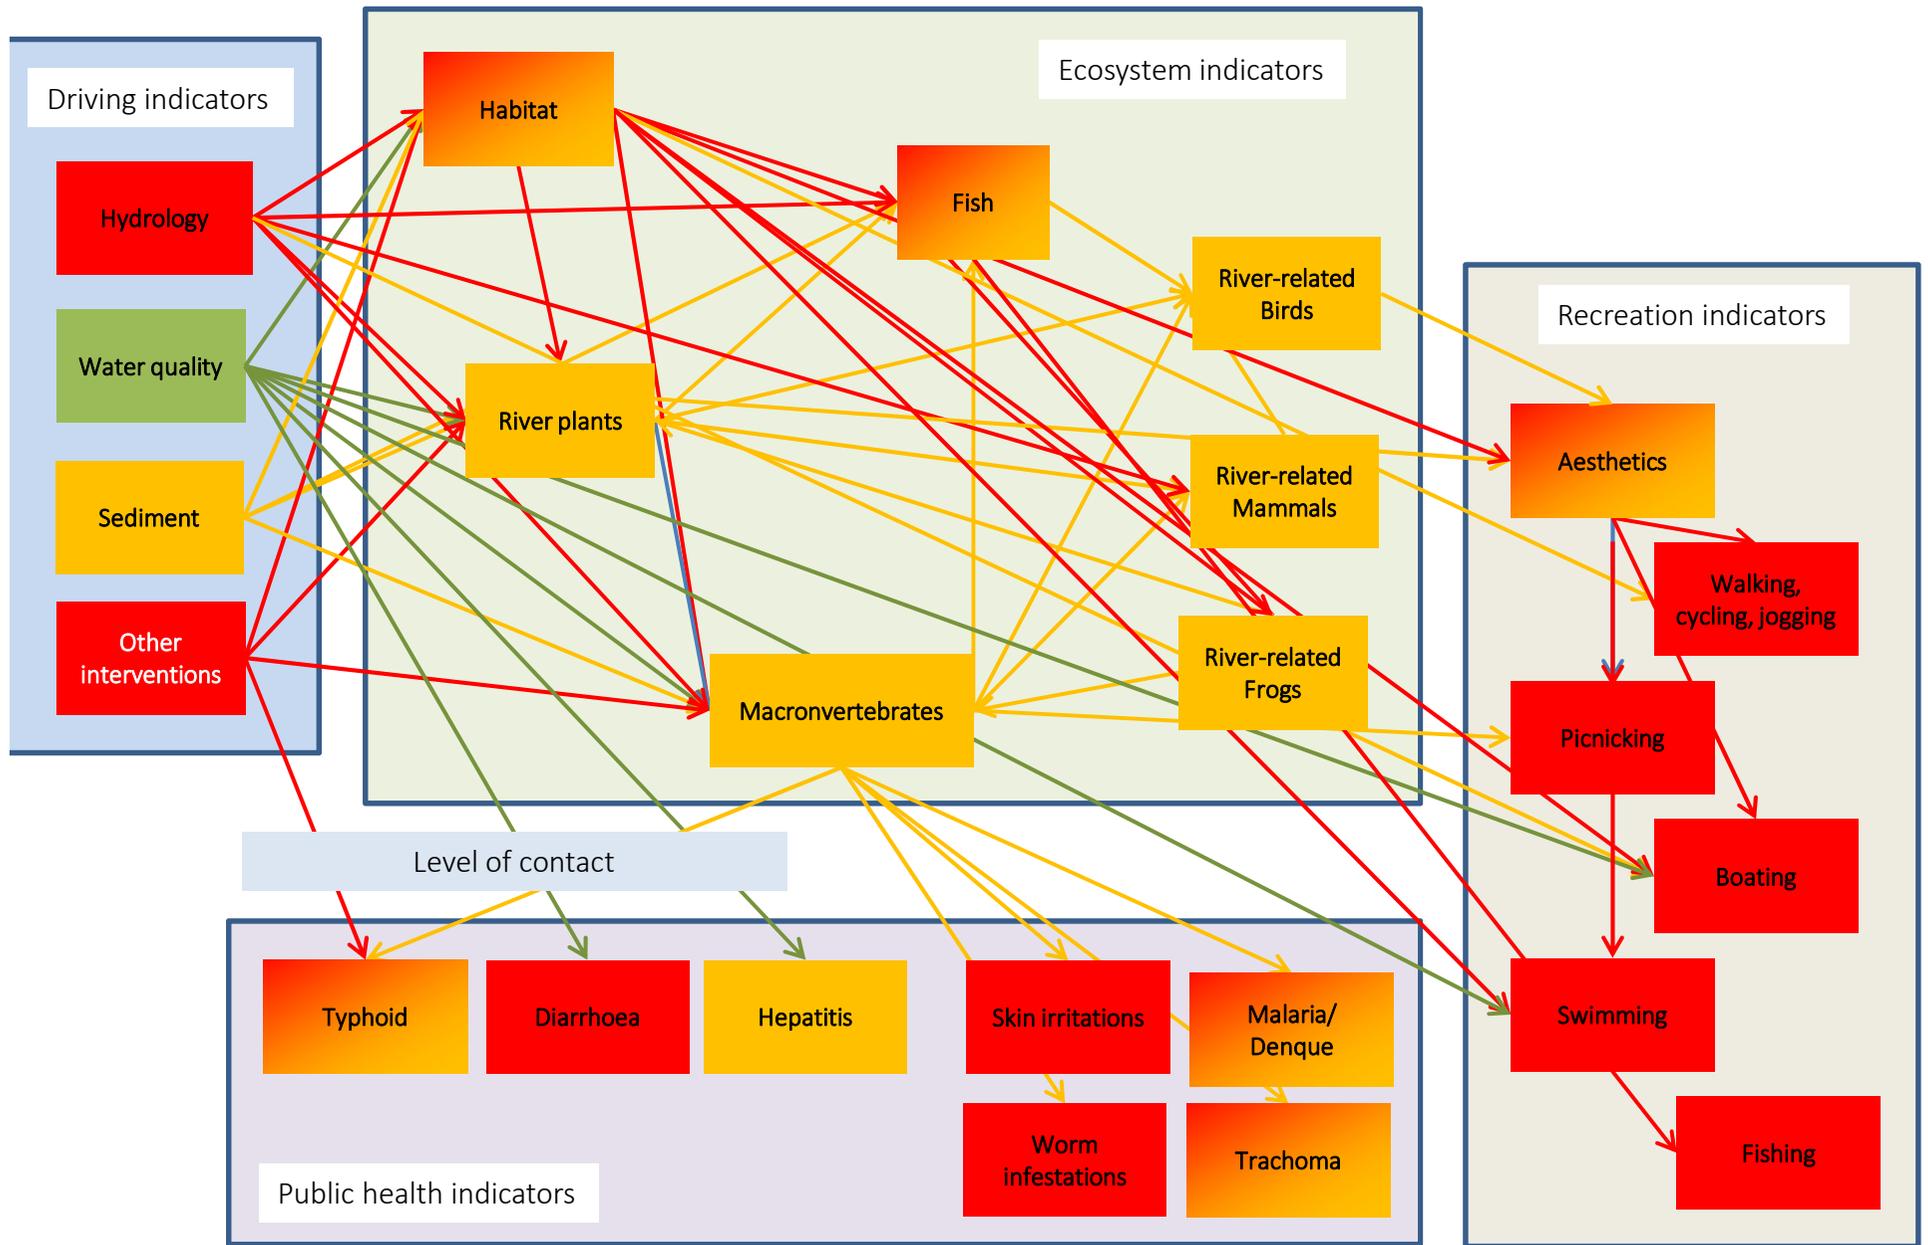

7. Select the preferred configuration of IUA Classes and Node categories

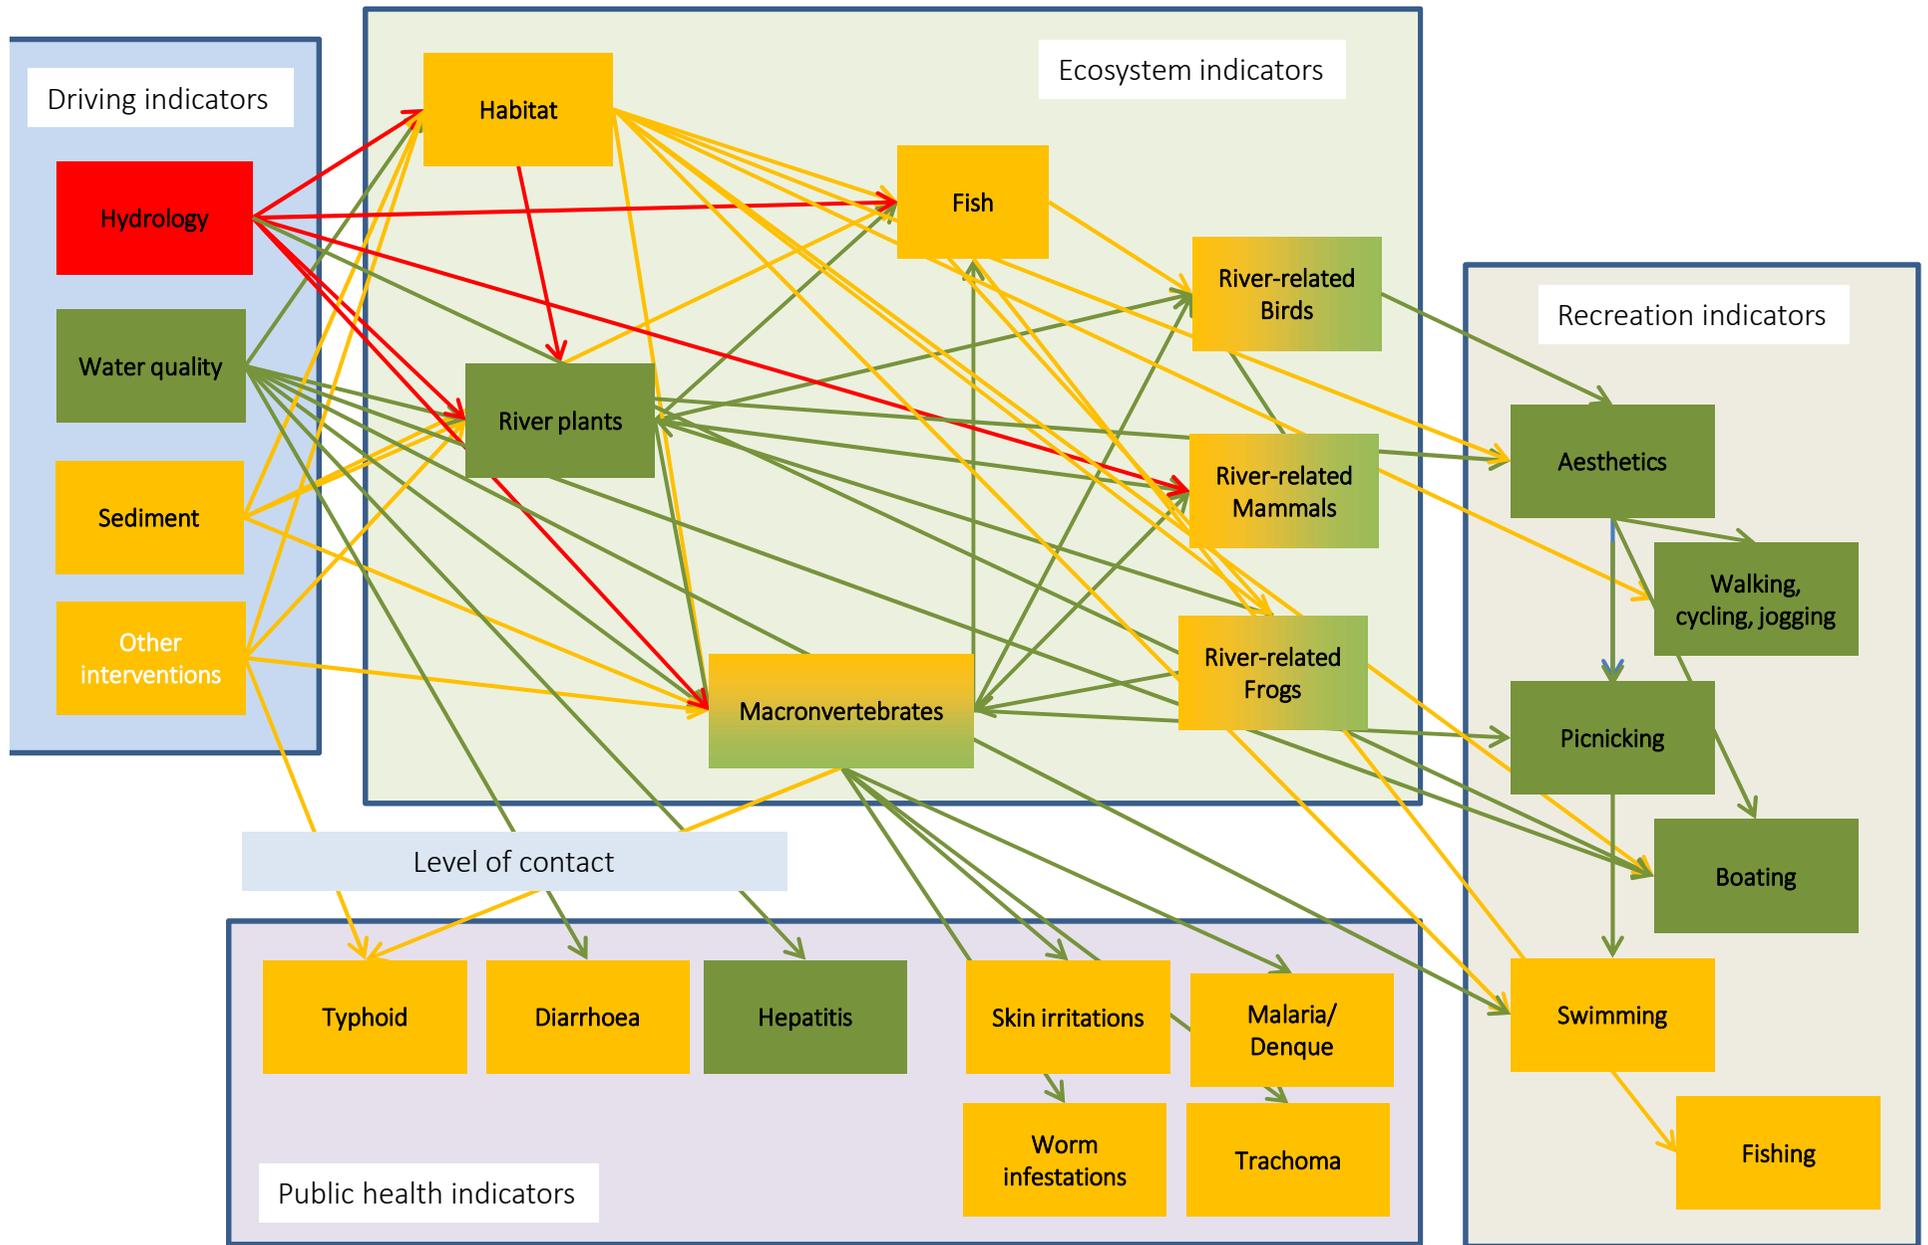

These become legally binding when published in the Government Gazette

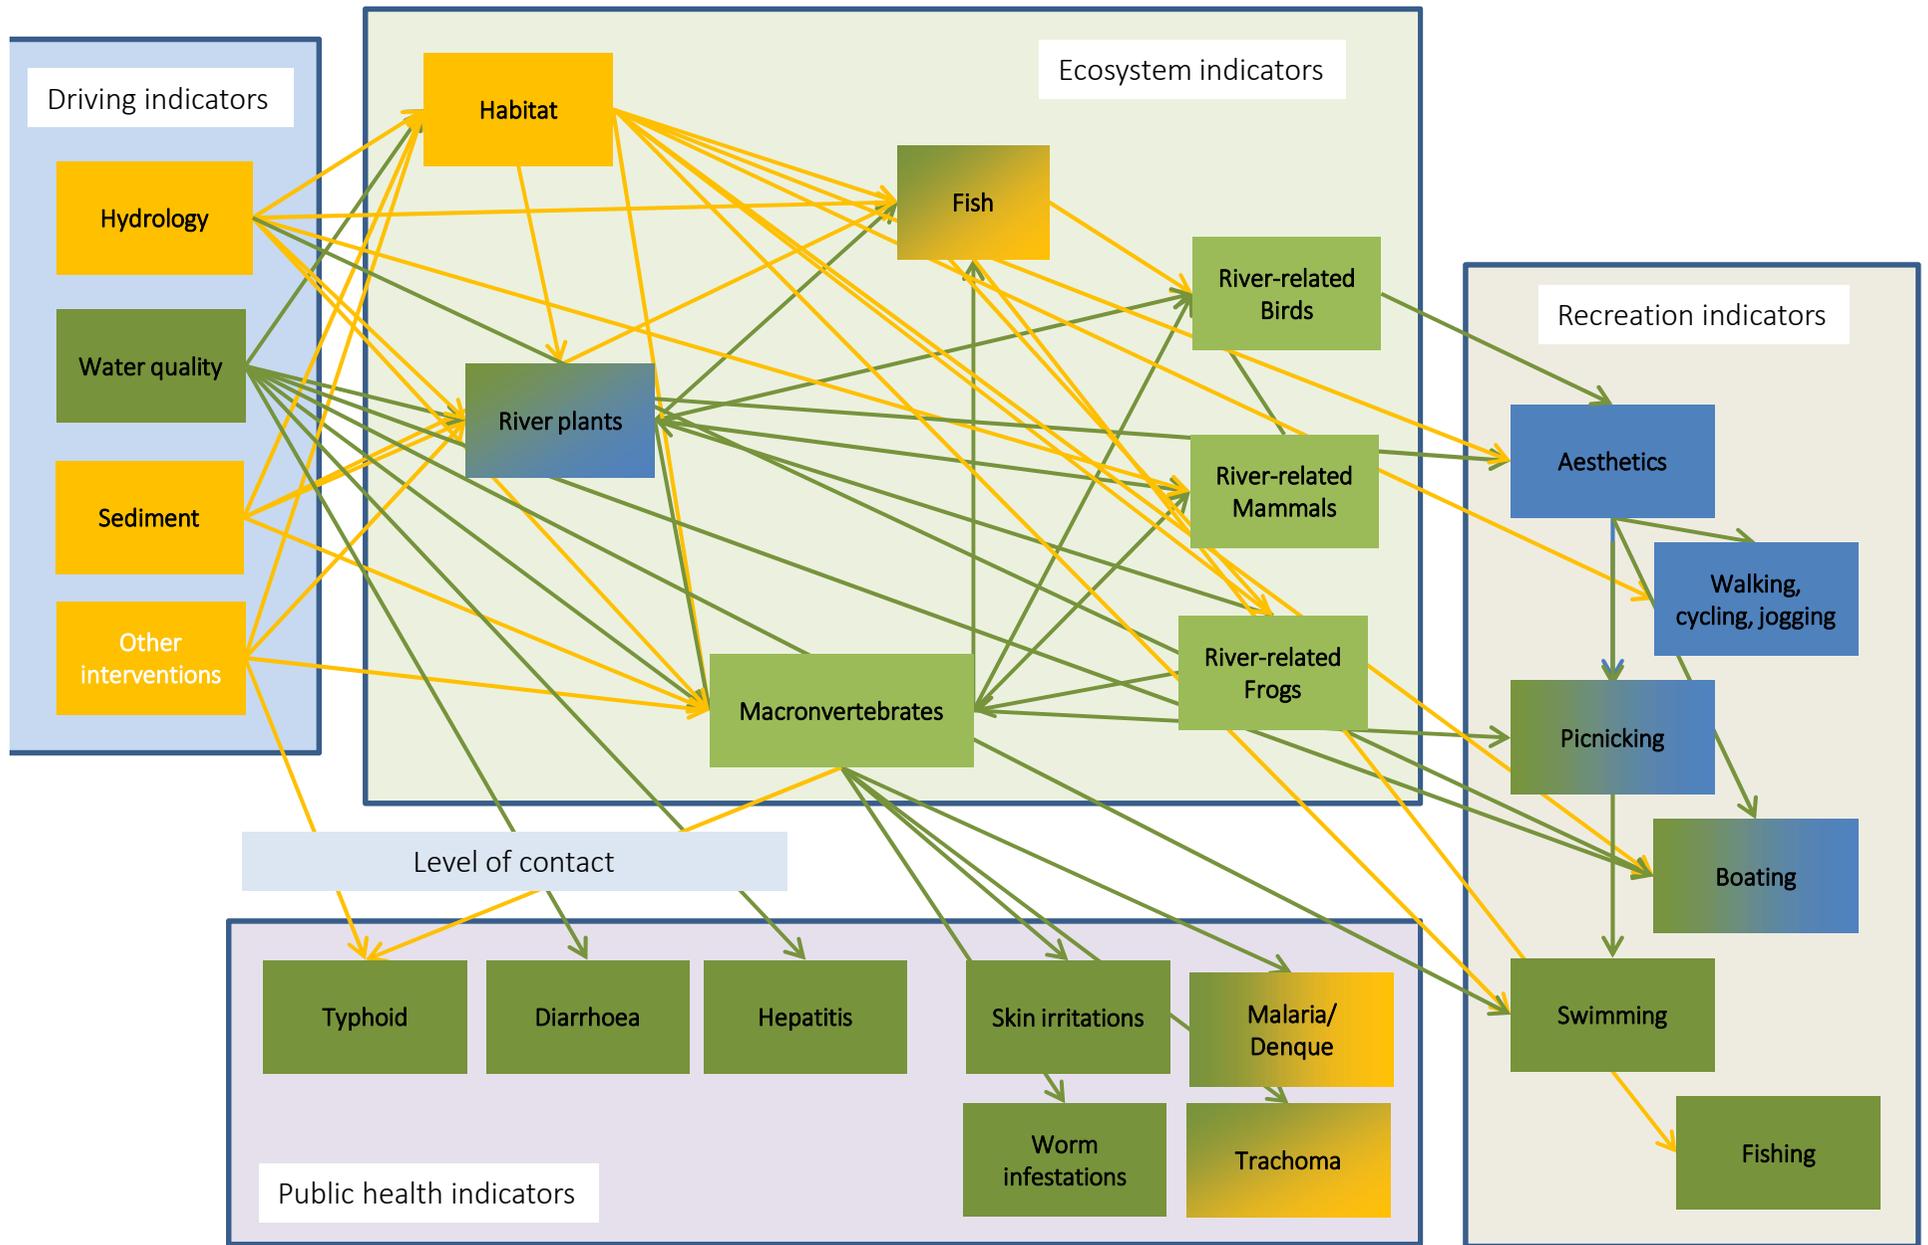

Thank you

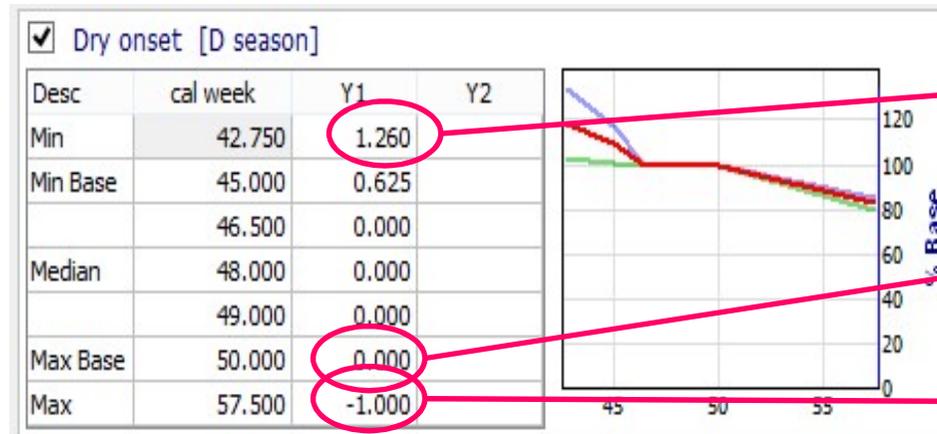

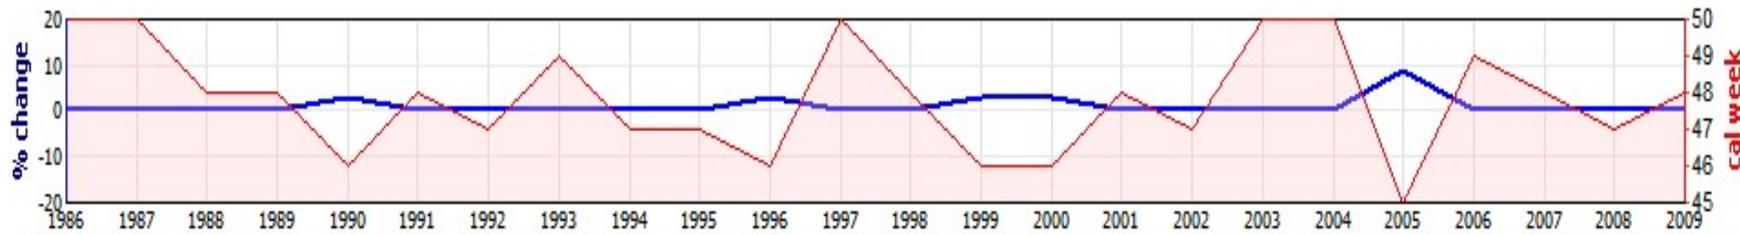

Rhithron fish vs onset of dry season

6 weeks earlier median
c. 15% increase

2 weeks later median
No change

10 weeks later median
c. 15% decrease

The onset of the dry season represents a time rhithron species are able to migrate to shallower areas with suitable substrate for spawning, earlier onset allows the fish greater time to migrate but late onset can disrupt spawning migration and maturation. Also if dry season starts earlier, it beneficial as fish can mature in less stressful conditions prior to spawning.
